Executive summary

Grapefruit and tomato metabolites for health

McGhie T, March 2013, SPTS No. 8182

Carotenoid and polyphenol concentrations were measured in the tomato 161 samples provided by the Central Tree Crops Research Trust. Lycopene (all-*trans*-lycopene) was present at the highest concentrations (not detected to 3.62 mg/100 g FW). β-carotene concentrations (not detected to 1.77 mg/100 g FW) and lutein concentrations (0.01 mg/100 g FW to 0.39 mg/100 g FW) were present at lower concentrations. Chlorophyll a was detected in 47 of the samples, with the highest concentration being 0.19 mg/100 g FW ('Green Raisan').

Tetra-*cis*-lycopene was found in seven of the samples, with the highest concentration being 5.36 mg/100 g FW ('Moonglow'). The presence of high concentrations of tetra-*cis*-lycopene may be of interest as it has recently been reported to be more bioavailable than the usual all-*trans*-lycopene and therefore the health benefit of these tomatoes may be greater than that of regular tomatoes. Tetra-*cis*-lycopene-containing tomatoes are orange/gold in colour and are readily distinguished from all-*trans*-lycopene containing tomatoes, which are red.

The tomato samples contained a large number of metabolites, and phenolic metabolites were specifically measured using liquid chromatography-high resolution mass spectrometry (LC-HRMS). Caffeic acid esters, such as chlorogenic acid, were present at the highest concentrations. The concentrations of the polyphenolic compounds were highly variable between tomato cultivars.

In grapefruit pith and juice, the polyphenolic compounds present at the greatest concentrations were the flavanones: naringin, narirutin, hesperidin, neohesperidin and eriocitrin. These compounds are typically present in grapefruit and other citrus fruits.

1 Introduction

A diet rich in fruits and vegetables is well known to reduce the risk of several diseases, such as cardiovascular disease and some cancers. Plant foods, including fruits such as tomato and grapefruit, contain chemical compounds (metabolites or phytochemicals), and it is these metabolites that are considered to be beneficial for the health of human consumers. The metabolite composition within each plant type varies by cultivar, climate and production system. There is also a view that modern fruit cultivars contain lower concentrations of health-promoting metabolites than older 'heritage' cultivars.

The aim of this project was to identify and measure metabolites in heritage cultivars of tomato and grapefruit that are considered to be beneficial to health. Metabolites were extracted from fruit samples with organic solvent and prepared for analysis by liquid chromatography-high resolution mass spectrometry (LC-HRMS).

2 Materials and methods

2.1 Sampling

Samples of tomato and grapefruit samples were collected by Mark Christensen, Central Tree Crops Research Trust, and sent by courier to Plant & Food Research, Palmerston North. All samples were frozen (-18°C) on arrival and stored frozen until analysis.

Tomato samples were homogenised using a Hobart food chopper, while being kept frozen using dry ice.

Frozen grapefruit were mounted on a skin peeler and the outer coloured layer removed. The underlying white pith layer was then removed for metabolite analysis. The fruit were allowed to thaw and then juiced in a domestic electric fruit juicer.

2.2 Tomato: carotenoid analysis

Portions of the homogenised samples were extracted with tetrahydrofuran:methanol, with the addition of anhydrous Na₂SO₄ and Na₂CO₃ and the carotenoid composition was measured by High Performance Liquid Chromatography (HPLC).

Authentic carotenoid standards (lutein, β-carotene, and lycopene) were used to identify and quantify each compound by retention time and spectral properties. Tetra-cis-lycopene was identified by reference to previously published research on tomatoes and was quantified as all-trans-lycopene equivalents.

2.3 Tomato: polyphenol analysis

Portions of the homogenised samples were extracted with ethanol/water/formic acid and the metabolite composition was measured by LC-HRMS.

Authentic polyphenol standards were used to identify and quantify compounds where possible. When a standard was not available, the component was identified by reference to previously published research on tomatoes and was quantified using a chemically similar compound.

2.4 Grapefruit: polyphenol analysis

Portions of the pith were extracted with ethanol/water/formic acid and the metabolite composition was measured by LC-HRMS. The juice was diluted with methanol and the metabolite composition was measured by LC-HRMS. All compounds were quantified as naringin equivalents.

3 Results and discussion

3.1 Tomatoes

Table 1 shows the concentrations of carotenoids present in the 161 samples provided. Lycopene (all-*trans*-lycopene) was present at the highest concentrations and these ranged from not detected (e.g. in 'Andean Tomato') to 3.62 mg/100 g FW ('Rosalita'). Tetra-*cis*-lycopene was found in seven of the samples, with the highest concentration being 5.36 mg/100 g FW ('Moonglow'). β -carotene concentrations ranged from not detected (e.g. in 'Pik's White') to 1.77 mg/100 g FW ('Surrey's Orange Delight'). Lutein concentrations ranged from 0.01 mg/100 g FW ('Black Master') to 0.39 mg/100 g FW ('Galapagos Island'). Chlorophyll a was found in 47 of the samples, with the highest concentration being 0.19 mg/100 g FW ('Green Raisan'). The presence of high concentrations of tetra-*cis*-lycopene may be of interest, as it has recently been reported to be more bioavailable than the usual all-*trans*-lycopene (Ishida et al. 2007; Burri et al. 2009) (see Appendix) and therefore the health benefit of these tomatoes may be greater than regular tomatoes. Furthermore, tetra-*cis*-lycopene-containing tomatoes are orange/gold in colour and are readily distinguished from all-*trans*-lycopene containing tomatoes, which are red.

Overall, the carotenoid concentrations show large variations and the concentration ranges are similar to those reported previously by PFR.

Table 1: Concentrations of carotenoids in tomato cultivars provided by the Central Tree Crops Research Trust.

lycopene = all-trans-lycopene

C⁴-lycopene = tetra-cis-lycopene

Tomatoes contain a large number if metabolites and many of these have been tentatively identified (Gomez-Romero et al. 2010). In these analyses, we have specifically measured phenolic metabolites using LC-HRMS. Caffeic acid esters, such as chlorogenic acid, were present at the highest concentrations. The concentrations of the polyphenolic compounds were highly variable among tomato cultivars.

Table 2: Concentrations of polyphenols in tomato cultivars provided by the Central Tree Crops Research Trust.

CouQA = *p*-coumaryl quinic acid

CafA = caffeoic acid

CafHex = caffeoylexhexoside

CQA = chlorogenic acid (caffeoylequic acid)

DCGA = dicaffeoylequic acid

Q=rut = quercurtin 3-rutinoside

Q=rutpent = quercurtin 3-rutinylpentoside

Nar = naringenin (or naringenin chalcone)

3.2 Grapefruit

The concentrations of the polyphenolic metabolites measured in the pith and juice of the 11 grapefruit samples provided are shown below in Table 3. The polyphenolic compounds present in both the pith and the juices at the greatest concentrations were the flavanones: naringin, narirutin, hesperidin, neohesperidin and eriocitrin. These compounds are typically present in grapefruit and other citrus fruits (Rouseff et al. 1987; Abad-Garcia et al. 2012).

Table 3: Concentrations of polyphenols in grapefruit selection cultivars provided by the Central Tree Crops Research Trust.

Name	Nar	Nar-rut	Nar-glu	Hes	neoHe	Eri	Pon
<i>Pith</i>							
Polyphenol Concentrations (ug/g FW)							
J. Fergusson, Drury	6679	2390	612	6602	2669	1487	235

Nar = naringin (*m/z* 579.171)

Nar-rut = narirutin (*m/z* 579.171)

Nar-glu = naringin glucoside (*m/z* 741.226)

Hes = hesperidin (*m/z* 609.181)

neoHes = neohesperidin (*m/z* 609.181)

Eri = eriocitrin (*m/z* 595.174)

Pon – poncirin (*m/z* 593.186)
